# Presentation

The plugin is an advanced tool for exporting data in CSV format, designed to simplify and automate the extraction of information from multiple database tables. It provides an intuitive interface that allows users to easily configure export options, customize data formats, and map fields according to their specific needs.

A step-by-step **wizard** guides users through the entire configuration process, ensuring a smooth and professional experience even for non-technical users.

# Usage Requirements

To use the CSV Export Module, the plugin must be properly installed and activated within the vtenext environment.

At the end of the installation process, it is essential to verify that no errors occurred and that the plugin appears as active in the *Installed Modules* section. An incomplete installation or a disabled plugin will prevent the export process from functioning correctly.

It is also necessary to ensure that the folder `storage/CSVExporter/` has the appropriate write permissions. Otherwise, the system will not be able to generate or save the exported CSV files.

Finally, some basic user knowledge is required, particularly in the following four areas:

1. **CRM module knowledge:** understanding the structure of the modules to be exported, the types of fields used, relationships between entities, and business logic.
2. **CSV format basics :** familiarity with field separators (`;`, `,`), text delimiters (`"`), line endings, and compatibility with software such as Excel, LibreOffice, or Google Sheets.
3. **Character encoding management:** using UTF-8 encoding to ensure correct display of accents, symbols, and special characters in exported files.
4. **File organization:** managing folder structures, applying consistent file naming, and implementing backup strategies to maintain order and data security.
